Mathematical Morphology first part: 2D

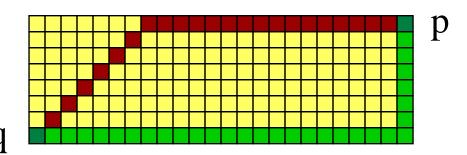

Mathematical Morphology

*Mathematical Morphology was developed in France (G. Motheron e J. Serra, Ecole des Mines) and in different form with the name Image Algebra in USA (S. R. Sternberg, Michigan University).

Preliminary statements

- → Let F={1} et F*={0} be the two sets constituting a binary image on a square plane tessellation. Let call them foreground and background respectively
- → Given two pixels p and q, having coordinates (i,j) and (h,k), the two distance functions d₄ (called city block) et d₈ (chessboard) are defined as:

$$d_4(p,q) = |i-h|+|j-k|$$
 $d_8(p,q) = \max\{|i-h|, |j-k|\}$

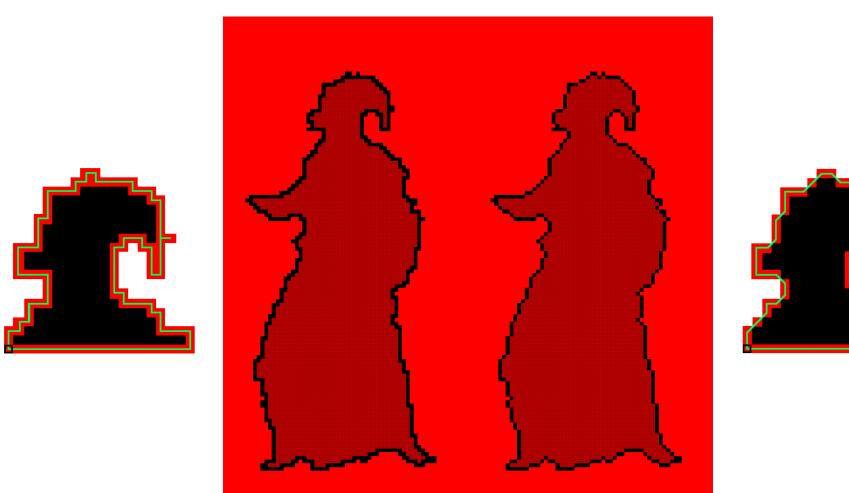

Preliminary statements

- The neighbors of pixel p are all pixels that have unitary distance from p
- → The set of neighbors constitutes the neighborhood of p. Depending on the adopted metric we consider the $N_4(p)$ or $N_8(p)$ neighborhoods.

- + A path of length n from p to q is a sequence of pixels $p=p_0, p_1, p_2,p_n=q$ that in the adopted metric has p_i neighbor of p_{i+1} , $1 \le i \le n$
- → A subset of F (or of F*) is connected if for each couple of pixels in the subset exist a path between them entirely belonging to the subset.
- → The contour C of an image F is the subset of F having unitary distance from F*

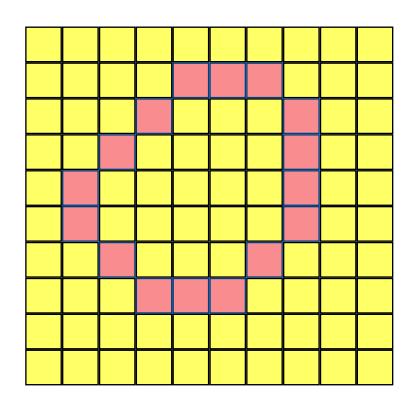

4 and 8 connectivity

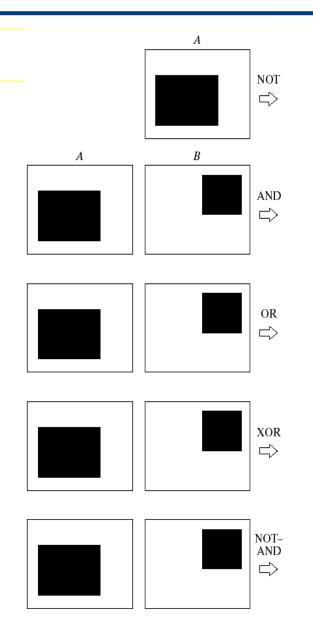

Topological Paradox

- → Contour in 8 connectivity
- → F and F* are separated only in 4 connectivity

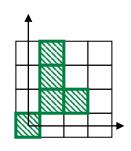

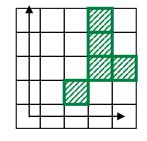

Logic operators between binary images

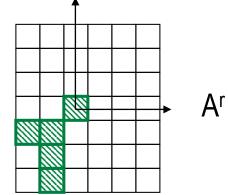

Preliminary Statements

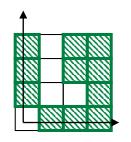

$$+$$
 A \subseteq Eⁿ, t \in Eⁿ

- $A_{(2,1)}$ + Translation of A by a vector t $A_t = \{ c \in E^n \mid c=a+t, a \in A \}$
 - → Reflection of A $A_r = \{ c \mid c = -a, a \in A \}$

 A^c

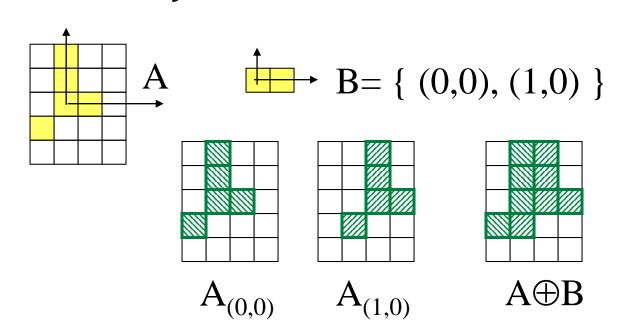

+ Complement of A

Minkowski sum (Dilation)

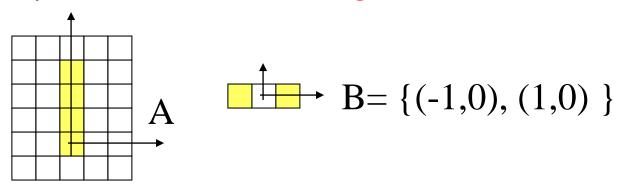

$$+A \oplus B = \{ c \in E^n \mid c=a+b, a \in A, b \in B \}$$

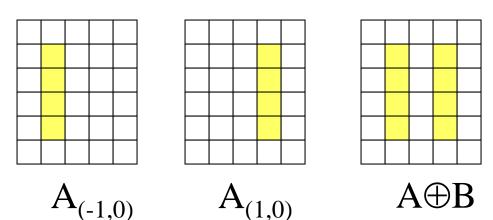

$$+A \oplus B = \bigcup A_b, b \in B$$

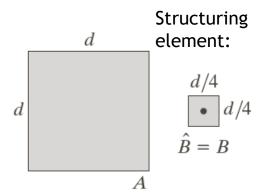

→ It can be easily shown that: $A \oplus B = B \oplus A$

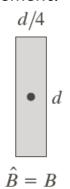

→ B is usually called structuring element

 $A \oplus B \oplus C$

Historically, certain computer programs were written using only two digits rather than four to define the applicable year. Accordingly, the company's software may recognize a date using "00" as 1900 rather than the year 2000.

Structuring element:

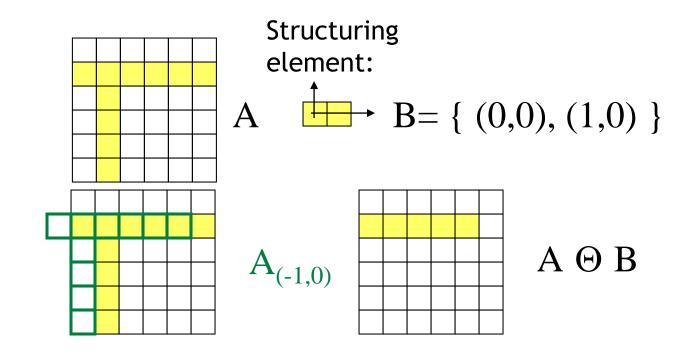

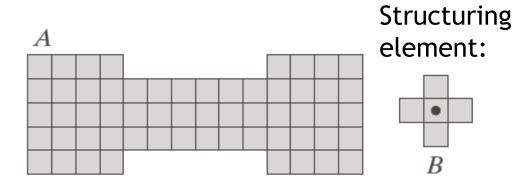

Minkowski difference (Erosion)

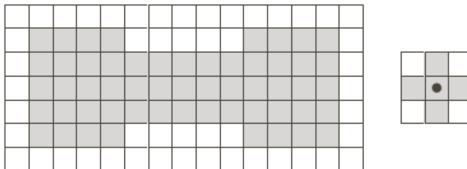

```
+ A\ThetaB = { c∈E<sup>n</sup> | c + b∈A, per ogni b∈B }

+ A\ThetaB = \cap A<sub>-b</sub> b∈B

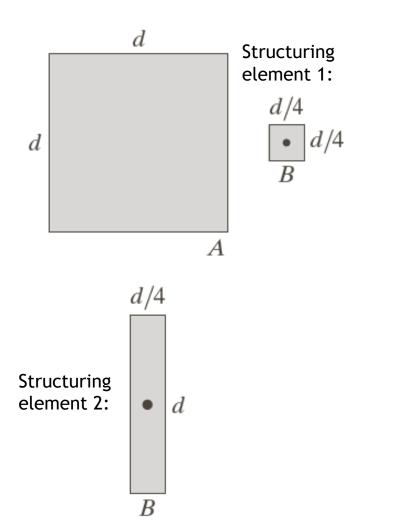

+ A\ThetaB = { c∈E<sup>n</sup> | B<sub>c</sub> \subset A
```

 $A \ominus B$

Eroded twice

Structuring element: .

Dilation (+) and Erosion (-) properties

$$A + \{\varnothing\} = A - \{\varnothing\} = A$$

$$A + \{a\} = A - \{a\}^r = A_a, \text{ translation}$$

$$A + B = (A^c - B^r)^c \qquad \text{Erosion and Dilation Duality Theorem: Dilation and Erosion transformation bear a similarity, what one does to image foreground and the other does for the image background.}$$

$$(A + B)^c = A^c - B^r \qquad \text{Similar but not identical to De Morgan rule in Boolean Algebra}$$

$$A + B_t = (A + B)_t$$

$$A - B_t = (A - B)_{-t}$$

Decomposition:
$$B=B_1+B_2+B_3+....+B_n$$

 $A+B=(...(((A+B_1)+B_2)+B_3)+....)+B_n$
 $A-B=(...(((A-B_1)-B_2)-B_3)-....)-B_n$

Dilation (+) and Erosion (-) properties

$$(A+B)+C=A+(B+C) \qquad (A-B)-C=A-(B+C)$$

$$(A\cup B)+C=(A+C)\cup(B+C) \qquad (A\cap B)-C=(A-C)\cap(B-C)$$

$$A+(B\cup C)=(A+B)\cup(A+C) \qquad A-(B\cup C)=(A-C)\cap(B-C)$$

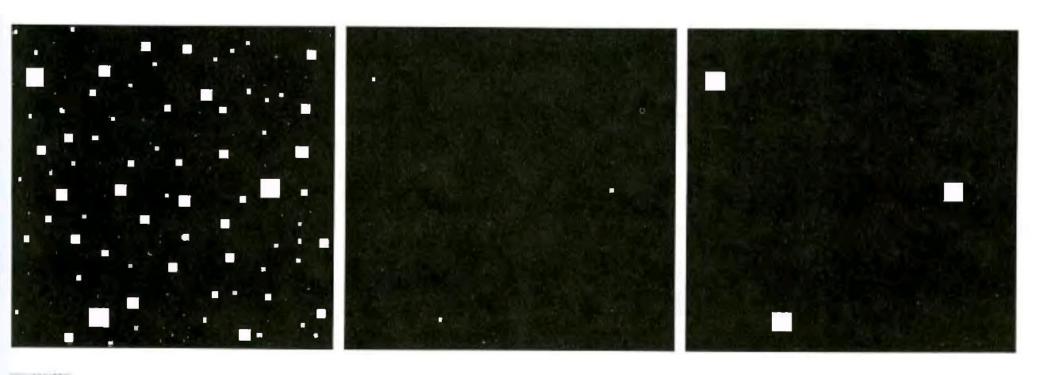

$$A\subseteq B\Rightarrow (A+C)\subseteq (B+C) \qquad A\subseteq B\Rightarrow (A-C)\subseteq (B-C)$$

$$B\subseteq C\Rightarrow (A-B)\supseteq (A-C)$$

$$(A\cap B)+C\subseteq (A+C)\cap(B+C) \qquad (A\cup B)-C\supseteq (A-C)\cup(B-C)$$

$$A-(B\cap C)\supset (A-C)\cup(B-C)$$

Erosion and Dilation summary

Opening

- + Erode, then dilate
- → Remove small objects, keep original shape

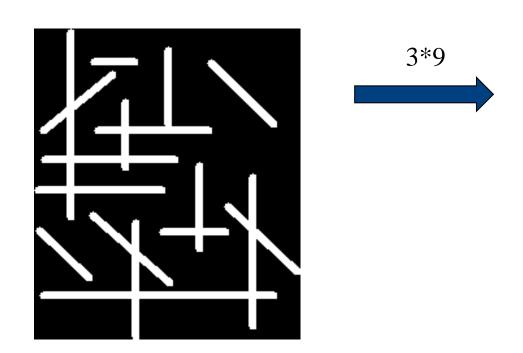

Structuring element: •

Before opening

Opening Example

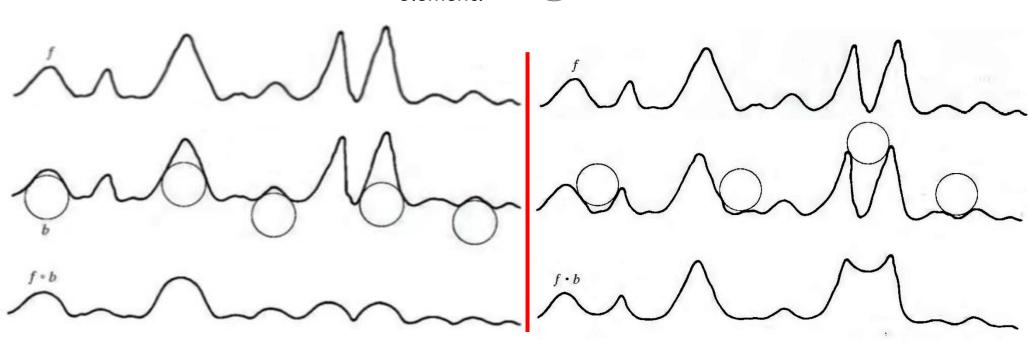

+3x9 and 9x3 Structuring Element

Opening and Closing: contour curvature

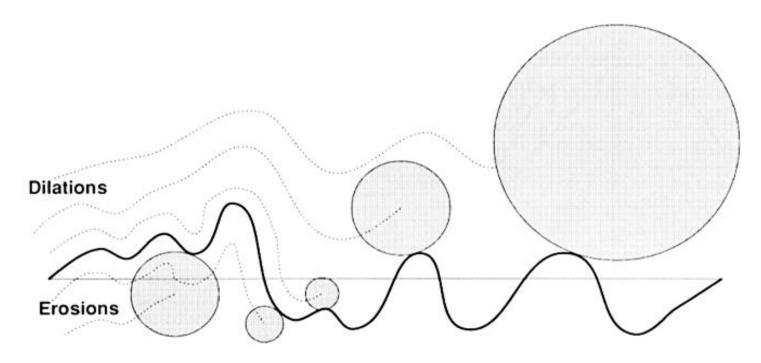

- Opening a picture is describable as pushing object B under the scan-line graph, while traversing the graph according the curvature of B
- The valleys usually remains in their original form
- Closing a picture is describable as pushing object B on top of the scanline graph, while traversing the graph according the curvature of B
- The peaks usually remains in their original form

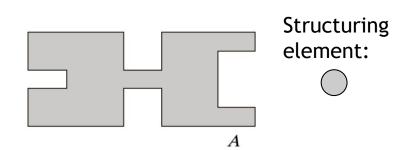

Structuring element:

The 'good' contour

- Opening and Closing operator with a circle as structural elements change the boundaries as shown in figure: closing extends the boundary as if a ball rolles over the outer border; opening restricts it rolling the inner border
- → The larger the circle the smoothed the result. The maximum resulting curvature is that of the structural element

Opening vs Closing

Opening Closing

Hit or Miss operator

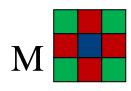

$$+A\otimes(J,K) = (A-J)\cap(A_c-K)$$

Two structuring elements J and K

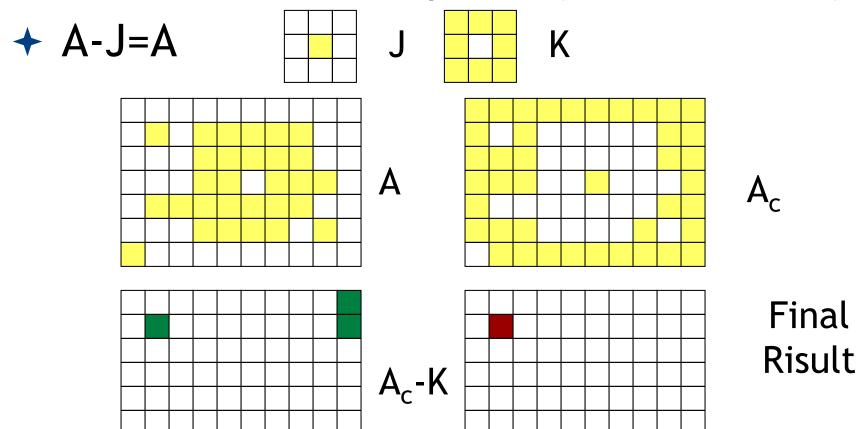

- → con il vincolo J

 K=Ø
- +Suitable for 'template' matching

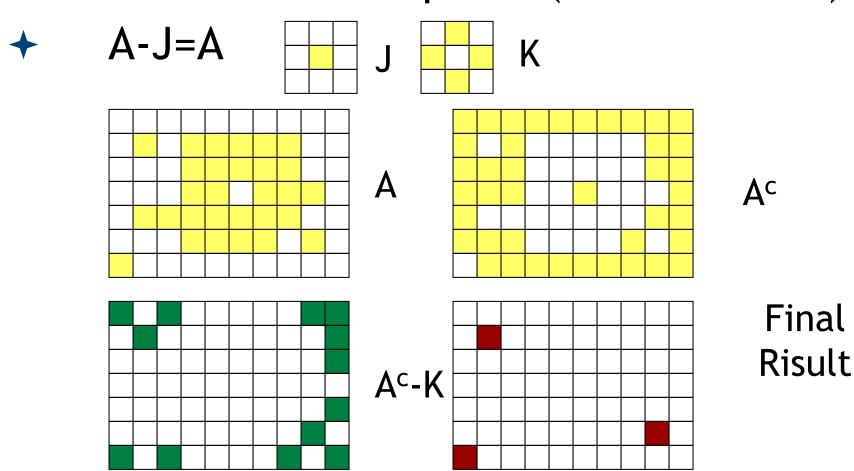

- → J and K can be seen as a single template with three values:
 - → Foreground points
 - →Background points
 - → Do not care points

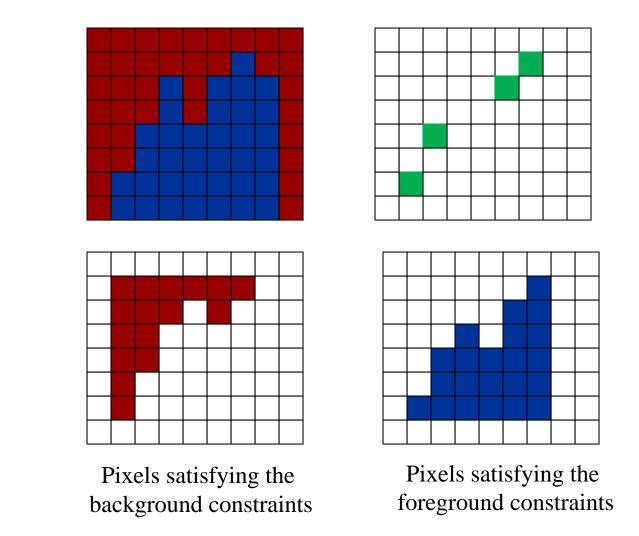

→ Search of isolated points(8-connection)

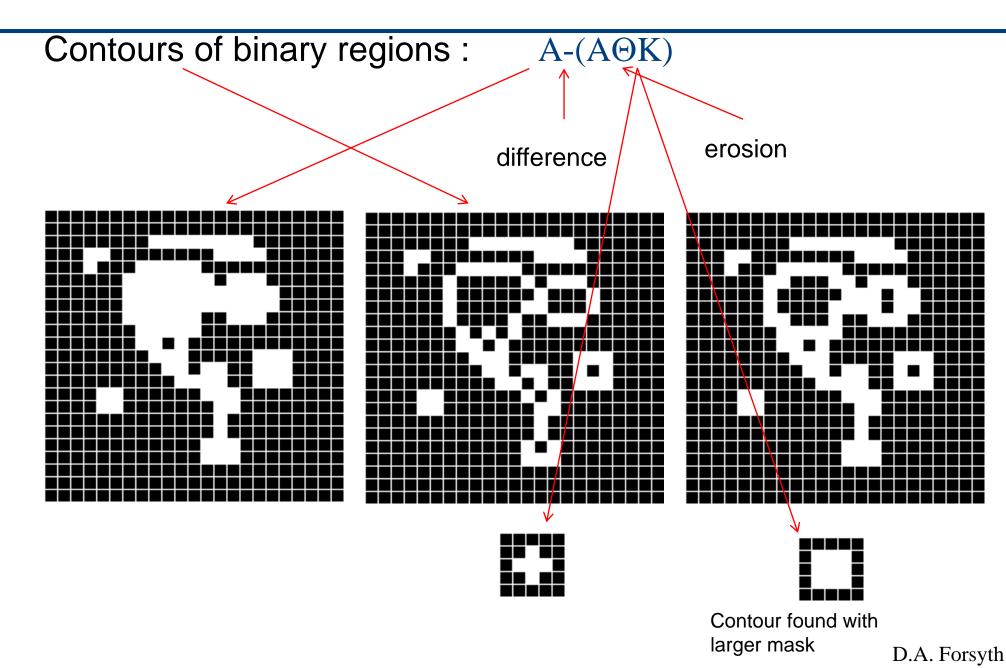

→ Search of isolated points(4-connection)

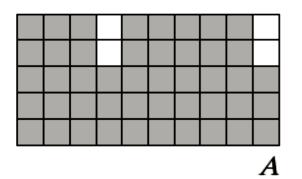

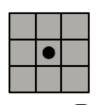

Using erosion to find contours

Example 1

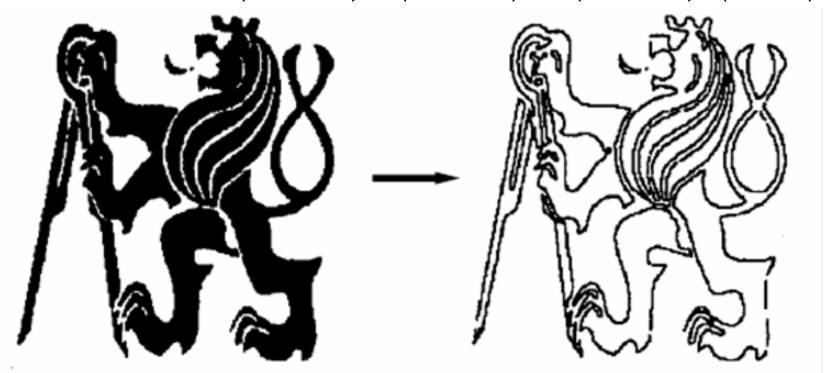

В

contour

Examples: Boundary Extraction

+ Contour

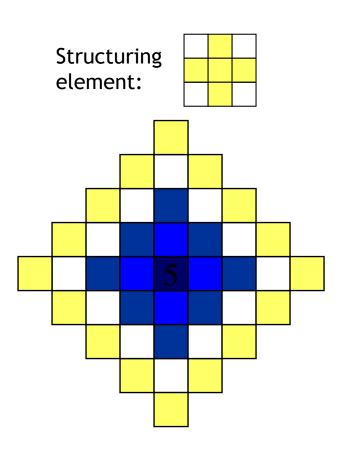

- +Internal: A- $(A\Theta K)$
- **+**External: $(A \oplus K)$ ∩Ā or $(A \oplus K)$ -A
- **→** Double: $(A \oplus K) \cap (\overline{A \odot K}) = (A \oplus K) \cdot (A \oplus K)$

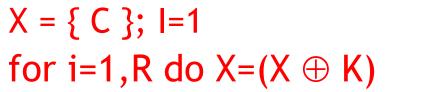

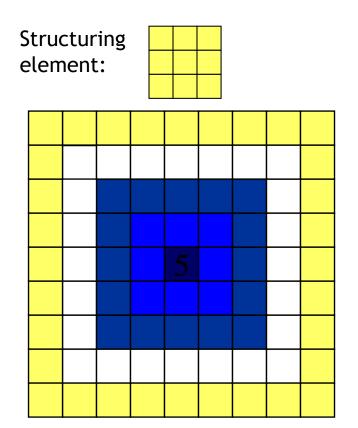

Example 2

Iteration: disks in 4 and 8 connectivity

C = center pixel

X = evolving image

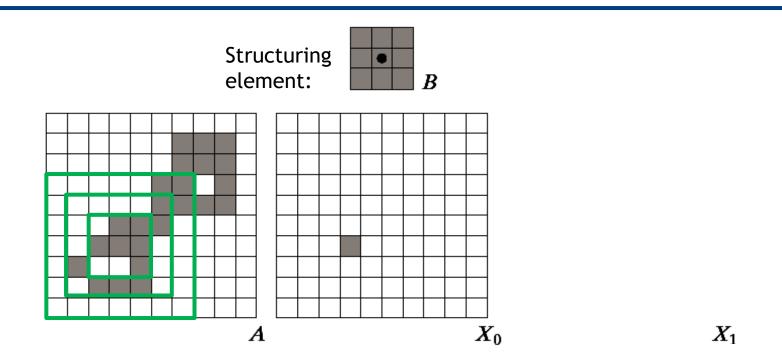

R = radius (4)

Recursion: Propagation

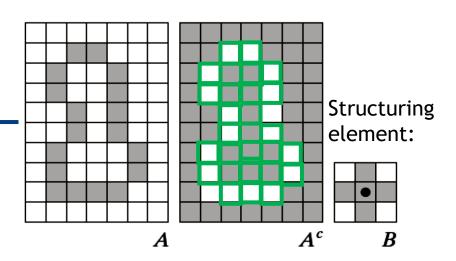

- → Propagation in a connected component
 - → Let A be a set containing one or more connected components (mask), and consider an array X_0 (of the same size of the array A) whose elements are 0s, except to a point of A foreground (marker).

X = evolving imageA = original imageK is the unitary circlein the adopted metric

Recursion example: Connected Components

 X_2 X_3 X_6 58 Gonzales-Woods

Hole Filling

Distance transform

DT implementation using dilation and addition operators:

$$+R = \emptyset$$

+while(A<>∅) do

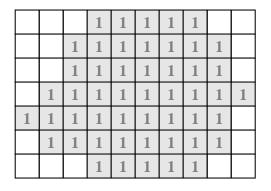

$$+R = R+A$$

$$+A = A \otimes K$$

+ done

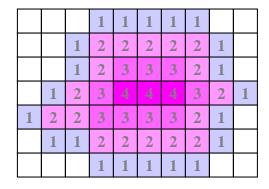

R = evolving image at the end DT

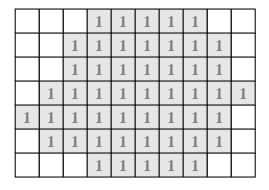

DT - algorithm

Structuring element:

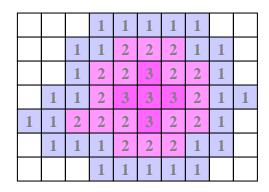

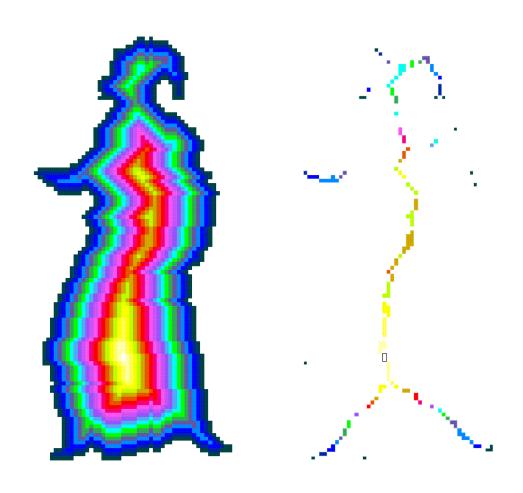

Structuring element:

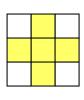

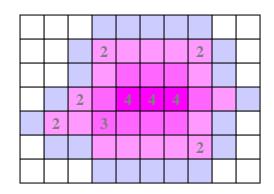

Distance transform and MAT

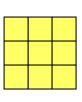

- → The Distance Transform (DT) is obtained by labeling all the pixels inside a binary object with their distance to the background
- Applying twenty iterations of the erosion operator (structural element: unit disk) twenty successive colored layers showing equi-distant contours from the background for a Manhattan distance metric are obtained
- ★ Every pixel has a color corresponding to its distance label which increases going inwards. In practice, this value represents the side of the greatest digital disk having its centre on this pixel, which is completely contained in the binary object.
- Any pattern can be interpreted as the union of all its maximal digital disks (local maximum in DT). A maximal disk is a disk contained in the object that is not completely overlapped by any other disk.
- ★ The set of the centers of the maximal disks with their labels, constitutes the MAT

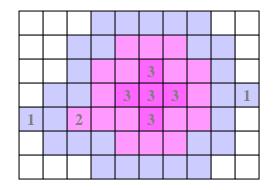

DT - local maxima

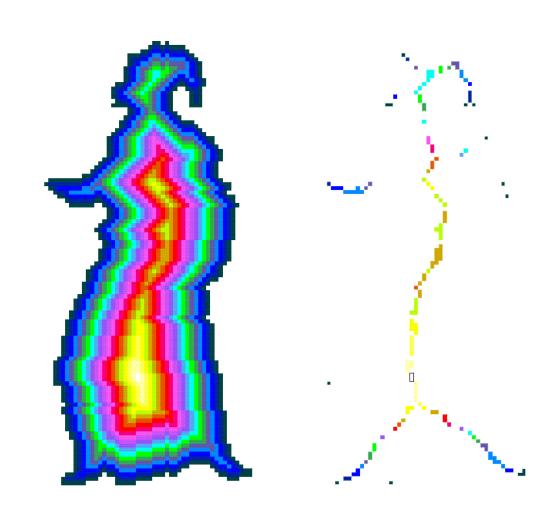

- → The local maxima set is a compact object representation
- The object can be rebuilt as union of the maximal digital disks

Distance transform and MAT

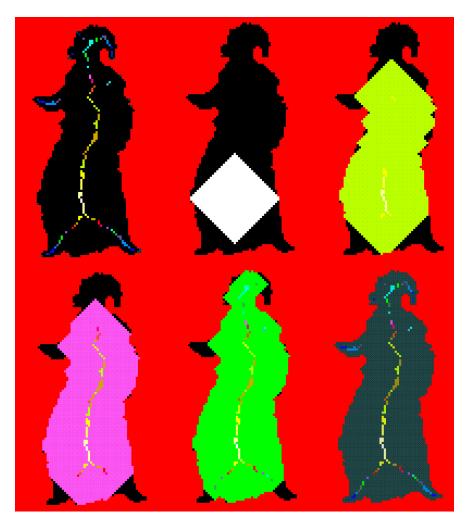

Reverting progressively MAT

- A procedure to derive the MAT from the DT is based on the comparison of neighboring labels to establish whether a local maximum exists
- This transform is complete in the sense that it is possible to revert it, so obtaining the original object back
- → This recovery process can be implemented by expanding every pixel belonging to the MAT, using the corresponding maximal disc whose size is given by the pixel label. The logical union of all such discs reconstructs the original object
- + This figure shows the progressive reconstruction, starting from the set of disks corresponding to the highest level (two white disks) until the sixth and last monk's profile, where discs, reduced to just one pixel, have been included
- This transform is compact since the full object may be described only by its labeled disk centers

$$U=\{\emptyset\}$$

 $\forall i,j: MAT_{i,j} > 0 \rightarrow U = U \cup D_{MAT_{i,j}}$

Distance between two points

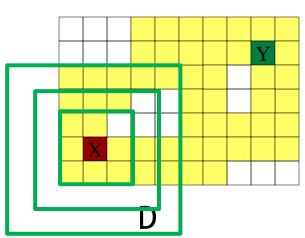

→ Distance between X,Y∈Z:

Structuring element:

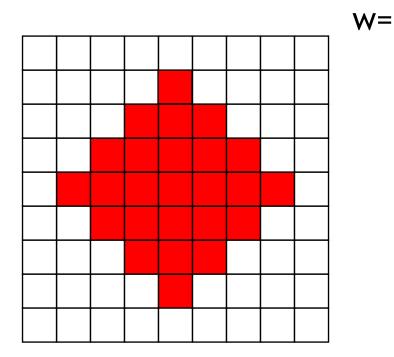

F

- + A = { X }; D=A Z={ \varnothing } A= evolving binary image
- → while(Y∉A) do
 F= original image (mask)
 - + Z = A
- Z= connected component
- + A = (A \oplus K) \cap F
- + D = D + A
- + Done
- → If $A \equiv (A \oplus K) \cap F$ and Y has not been already reached: Z is not connected and Y is not reachable from X
- Following a path of max gradient we can find one of the minimum paths between X, Y

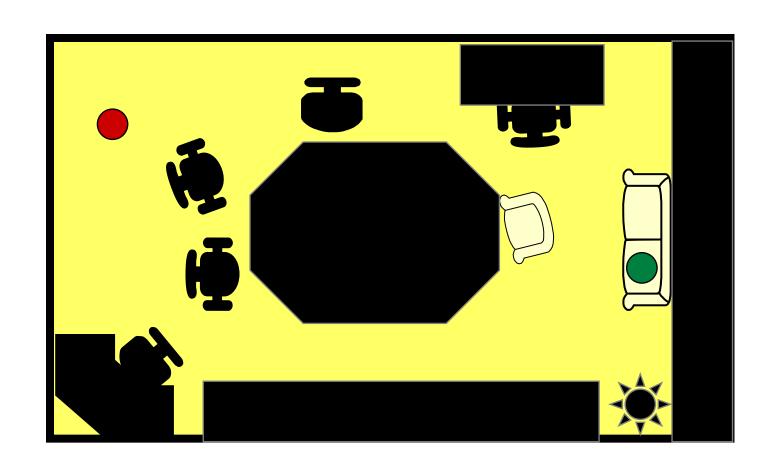

Weighted DT

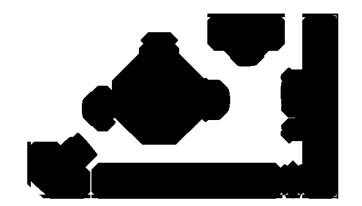

- In this case all neighbors are not considered at the same distance (e.g. 8-connectivity)
- ★ Example: a good approximation to the Euclidean distance in 8-connectivity (the result is about doubled) is given by:

			2				
		2	2 3 5 6 5 3 2	2			
	2	2 3 5 3 2	5	2 3 5 3 2	2		
2	2 3 2	5	6	5	2 3 2	2	
	2	3	5	3	2		
		2	3	2			
			2

8-Convex Hull

- → A set A is said to be convex if the straight line segment joining any two points in A lies entirely within A.
- → The convex hull is the minimum n-sided convex polygon that completely circumscribes an object, gives another possible description of a binary object. An example is given in figure where a constrained 8-sided polygon has been chosen to coarsely describe the monk silhouette.
- → To obtain the convex hull a simple algorithm propagates the object along the eight (more generally 2n) orientations and then: i) logically OR the opposite propagated segments; and ii) logically AND the four (more generally n) resulting segments. The contour of the obtained polygon is the convex hull.

Use of thickening: Convex hull

★ Convex hull: union of thickenings, each up to idempotence B^2 B^3 B^4 B^1 Thickening Union of Original with first shape four mask thickenings D.A. Forsyth

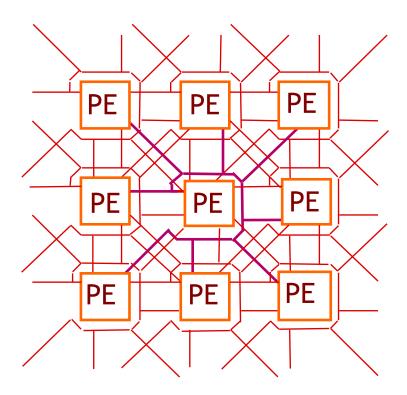

Example of using convex hull
